

Documentation Report For Banking System

Introduction

The Bank Management System is a simple program developed using the C language to handle basic banking activities. This project helps simulate how a bank stores and manages customer information in a digital format. By using structures and file handling, the program saves account details permanently so that they can be retrieved and updated later. The system offers a menu that allows the user to create an account, deposit money, withdraw money, and check the balance. Its straightforward design makes it easy to understand and helps students learn how real-life applications manage data.

Objectives

The main aim of this project is to build a basic and functional banking system using core concepts of C programming. Through this project, the goal is to perform essential operations such as creating new accounts, updating balances after deposits or withdrawals, and viewing account information. Another objective is to provide practical experience in file handling, which is a crucial part of storing data permanently in C. Additionally, the project helps in understanding how to organize a program using functions and user-defined structures in a clean and modular way.

Description of the Code

The program uses a structure named `account` to store the customer's name, account number, and balance. Each task is handled through a separate function. The `createAccount()` function collects customer details and writes them to a file so that the data remains saved even after the program ends. The `deposit()` and `withdraw()` functions try to find the account in the file and update its balance based on the user's input. The `checkBalance()` function reads the file and displays the account details when the correct account number is entered. A menu-driven loop in the main function allows users to choose the operation they want to perform. While the program works as a beginner-level banking system, some parts of the file-update logic can be improved for more accurate record handling.

Conclusion

This Bank Management System project provides a practical introduction to how banking operations can be handled through programming. It successfully demonstrates the use of structures, functions, and file handling in C to build a simple but functional application. Although there is room for improvement in the way account details are updated in the file, the project gives a clear

understanding of how data storage and retrieval work in real systems. With enhancements like proper record modification, better validation, and cleaner file handling, this program can be expanded into a more polished and reliable banking application.
